TITLE: Medication Administration via Metered Dose Inhalers and Aerochambers Versus Nebulizers For Adult Patients: Clinical Effectiveness

DATE: 13 November 2013

RESEARCH QUESTION

What is the comparative effectiveness of medication administration via metered dose inhalers (MDI) and aerochambers versus nebulizers for adult patients in health care settings?

KEY MESSAGE

Two systematic reviews, two RCTs, and two non-randomized studies were identified regarding the comparative effectiveness of medication administration via metered dose inhalers and aerochambers versus nebulizers for adult patients in health care settings.

METHODS

A limited literature search was conducted on key resources including PubMed, The Cochrane Library (2013, Issue 10), University of York Centre for Reviews and Dissemination (CRD), ECRI (Health Devices Gold) databases, Canadian and major international health technology agencies, as well as a focused Internet search. No filters were applied to limit the retrieval by study type. The search was also limited to English language documents published between Jan 1, 2008 and Nov 4, 2013. Internet links were provided, where available.

The summary of findings was prepared from the abstracts of the relevant information. Please note that data contained in abstracts may not always be an accurate reflection of the data contained within the full article.

RESULTS

Rapid Response reports are organized so that the higher quality evidence is presented first. Therefore, health technology assessment reports, systematic reviews, and meta-analyses are presented first. These are followed by randomized controlled trials (RCTs), non-randomized studies, economic evaluations, and evidence-based guidelines.

Disclaimer: The Rapid Response Service is an information service for those involved in planning and providing health care in Canada. Rapid responses are based on a limited literature search and are not comprehensive, systematic reviews. The intent is to provide a list of sources of the best evidence on the topic that CADTH could identify using all reasonable efforts within the time allowed. Rapid responses should be considered along with other types of information and health care considerations. The information included in this response is not intended to replace professional medical advice, nor should it be construed as a recommendation for or against the use of a particular health technology. Readers are also cautioned that a lack of good quality evidence does not necessarily mean a lack of effectiveness particularly in the case of new and emerging health technologies, for which little information can be found, but which may in future prove to be effective. While CADTH has taken care in the preparation of the report to ensure that its contents are accurate, complete and up to date, CADTH does not make any guarantee to that effect. CADTH is not liable for any loss or damages resulting from use of the information in the report.

It may not be copied, posted on a web site, redistributed by email or stored on an electronic system without the prior written permission of CADTH or applicable copyright owner.

Links: This report may contain links to other information available on the websites of third parties on the Internet. CADTH does not have control over the content of such sites. Use of third party sites is governed by the owners’ own terms and conditions.
Two systematic reviews, two RCTs, and two non-randomized studies were identified regarding the comparative effectiveness of medication administration via metered dose inhalers (MDI) and aerochambers versus nebulizers for adult patients in health care settings. No relevant health technology assessments were identified. Additional references of potential interest are provided in the appendix.

OVERALL SUMMARY OF FINDINGS

One systematic review\(^1\) compared the effectiveness of beta-agonist delivery via MDIs with an aerochamber with nebulizers for the treatment of acute asthma. Six of the 39 trials included in the review involved inpatients and there were more children included in the analysis than adults. For adults, the length of stay, peak flow, and expiratory volume were all similar between the two methods and the authors concluded there was no significant difference between the two delivery methods.

One systematic review\(^2\) compared MDIs and nebulizers for the delivery of aerosol bronchodilators for mechanically ventilated adults in critical care. Limitations of the data meant meta-analysis could not be undertaken and the authors concluded that there was not sufficient evidence to support either delivery method. One RCT\(^3\) compared salmeterol and fluticasone delivered via a MDI with spacer with ipratropium, terbutaline, and budesonide via nebulizer for mechanically ventilated patients with chronic obstructive pulmonary disease (COPD). No significant differences in minute ventilation, expiratory pressure, or airway resistance were observed between groups.

One crossover RCT\(^4\) compared intermediate dose ipratropium and salbutamol via MDI with spacer and high dose ipratropium and salbutamol via nebulizer for patients with COPD. There were no significant differences in clinical outcomes reported between the two methods. The authors suggested stepping up the intermediate dose via MDI before moving on to nebulized therapy. One non-randomized study\(^5\) examined lung deposition of salbutamol via MDI with spacer or nebulizer following an acute exacerbation of COPD or asthma and found no significant differences in urinary salbutamol excretion or forced expiratory volume between the two delivery methods.

A non-randomized crossover study\(^6\) examined the effects of bronchodilator therapy via MDI or nebulizer on inspiratory lung function parameters. Lung function parameters improved significantly following treatment with both devices. The authors concluded that the MDI with spacer was a better method of administration than the nebulizer for patients with stable COPD.
