GENERAL POINTS

In 2010, among the elderly living in long-term care facilities (LTCFs):
- 41% were over 85 years old (MSSS, 2010);
- 68% suffered from severe loss of autonomy (MSSS, 2010);
- 60% to 80% were affected by some form of cognitive impairment (MSSS, 2010).

Infection management in this population should always be adapted to the level of care determined by the physician after a consultation with the patient or the patient’s representative. The availability of laboratory tests, variability of medical coverage and capacity to administer IV antibiotics should also be considered.

FACTORS ASSOCIATED WITH GREATER SUSCEPTIBILITY TO INFECTIONS AND COMPLICATIONS

- Decreased immune defences associated with age
- Protein-energy undernutrition
- Medications (antibiotics, immunosuppressants, steroids) and polymedication
- Decreased cognitive and physical abilities
- Recent hospital stay
- Comorbidities (cancer, diabetes, COPD, dysphagia)
- Peripheral vascular disease
- Increased risk of exposure to pathogens
- Confinement to bed, immobility
- Presence of exogenous material (catheter, dentures, prostheses, etc.)
- Proximity to other residents, and staff movements between patient care units

INFECTION DIAGNOSIS

MAIN CLINICAL FEATURES THAT MAY INDICATE THE PRESENCE OF INFECTION

- Fever or hypothermia (temperature sometimes normal)
- Failure to cooperate with staff
- May be atypical and nonspecific: delirium, agitation, lethargy, falls, loss of autonomy when performing activities of daily living (ADLs) decreased food intake and hydration
- May be nonexistent in very old or severely impaired subjects

Fever in elders living in long-term care facilities

- Temperature higher than 37.8°C when taken orally
- More than two oral temperature readings over 37.2°C, or 37.5°C rectally
- More than two oral temperature readings at least 1.1°C over the baseline oral temperature (which may be lower than 37.2°C in elderly patients)
## Most Common Infectious Causes of Fever

<thead>
<tr>
<th>Causes</th>
<th>Predispositions</th>
<th>Prevention Principles</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Viral infections</strong></td>
<td>• Endemic period (influenza)</td>
<td>• Refer to the public health protocol</td>
</tr>
<tr>
<td></td>
<td>• Vaccinations: against influenza, recommended on an annual basis</td>
<td></td>
</tr>
<tr>
<td><strong>Bacterial respiratory tract infections (pneumonia)</strong></td>
<td>• COPD • Weakened gag reflex • Dysphagia • Poor oral hygiene</td>
<td>• Vaccinations: against <em>pneumococcus</em>, recommended at least once during lifetime</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Place the patient in a half-sitting position (30 degrees)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Maintain good oral hygiene</td>
</tr>
<tr>
<td><strong>Urinary tract infections</strong></td>
<td>• Diabetes • Incomplete bladder emptying • Presence of a urinary catheter • Fecal incontinence/constipation</td>
<td>• Long-term prophylactic antibiotic therapy not recommended due to unproven effectiveness and an increase in microbial resistance</td>
</tr>
</tbody>
</table>
|                                 |                                                               | • Limit the use of permanent urethral catheters:  
  ▪ Establish a bladder-voiding schedule  
  ▪ Promote hydration  
  ▪ Up to 40% could be unnecessary (used to control incontinence or monitor diuresis)  
  ▪ When possible, choose intermittent catheterization over permanent catheters |
| **Skin and soft-tissue infections** (cellulitis, wound superinfection, pressure ulcer) | • Diabetes • Protein-energy undernutrition • Poor skin health (maceration, dryness) • Immobility, confinement to bed • Increased skin fragility • Edema (peripheral vascular disease) • MRSA carrier | • Limit the severity of the peripheral edema (use of diuretics or compression stockings, elevation of the extremities)  
• Frequent repositioning of bedridden patients  
• Protection of skin integrity  
• Nutritional status optimization |
| **Gastrointestinal infections**  | • Recent antibiotic treatment • Chemotherapy • Gastrointestinal surgery • Enteral nutrition • Inadequate hygienic practices • Recent hospital stay | • *Clostridium difficile*-associated diarrhea:  
  ▪ Avoid using antibiotics over a long period (avoid chronic use, define duration of treatment based on the indication)  
  ▪ Stop ongoing antibiotic treatment if initially asked cultures are negative and if there is a clinical correlation  
  ▪ Isolation is recommended for patients presenting with *Clostridium difficile*-associated diarrhea  
  ▪ Using probiotics is **not recommended** for now, due to the lack of supporting clinical data concerning its effectiveness |

1. Refer to the health care facility protocol in effect.

### Factors Associated with Greater Susceptibility to Adverse Reactions
- Increased frailty
- Digestive disorders, disruption of intestinal flora
- Polymedication
- Decreased renal or hepatic functions

### Risks Associated with the Use of Antibiotics in the Elderly
- Antibiotic resistance
- Drug interactions
- Adverse reactions
- *Clostridium difficile*-associated diarrhea

</tbody>
</table>

¹ Refer to the health care facility protocol in effect.

NB: Cultures from the wound's surface are not indicated for diagnosis (poor correlation with the causal agent due to its colonization by several bacteria)
**TREATMENT PRINCIPLES**

- Consider the following elements when treating the elderly living in LTCFs:
  - Initial treatment is based on:
    - Signs and symptoms observed (indication, severity)
    - Patient history (previous pathogens, antibiotics taken during the previous three months, resistance and level of care)
    - Most frequently encountered pathogen for the established diagnosis
    - Facility's list of medications
  - Treatment response may be delayed in some cases.

- **Minimize empirical use of broad-spectrum antibiotics**
  - Adjust the antibiotic treatment once the pathogen has been identified (prefer narrow-spectrum antibiotics)

- **Avoid using antibiotics over a long period** (prophylaxis or chronic use)
  - Duration of treatment determined based on indications (when possible) and patient re-evaluation

- Determine:
  - Interactions (e.g., iron intake, calcium, tube feeding, IPP)
  - The appropriate formulation (crushed tablets or liquid form may be necessary)

- Choose the minimal dose and duration of treatment recommended, based on infection type and severity, and on the pathogen involved (if known):
  - Adjust dosage based on creatinine clearance:
    \[
    \text{Creatinine clearance (ml/min)} = \frac{(140 \text{ - age}) \times \text{ideal weight (kg)} \times 1.2}{\text{serum creatinine (μmol/l)}} \times 0.85 \text{ for women}
    \]

  - NB: Creatininemia is not a good marker due to the reduced muscle mass observed in the elderly.

- **The patient's state must improve within 72 hours of treatment (objective signs, such as lower temperatures).**
- Stop ongoing antibiotic treatment if initially asked cultures are negative and if there is a clinical correlation.

- **DO NOT TREAT ASYMPTOMATIC BACTERIURIJA:**
  - A positive analysis or urine culture is considered a sign of urinary tract infection, which should be treated only when urinary symptoms (burning sensation when urinating, dysuria, urge to urinate, hematuria, de novo or increased incontinence) or systemic clinical features (fever) are present.
  - Screening and treatment of asymptomatic bacteriuria in diabetic patients is not recommended, as these measures do not prevent complications associated with urinary tract infections.
  - Urine cultures and urinalysis are not indicated for the elderly who present with changes in the smell, colour or turbidity of their urine without any associated urinary symptom: such changes are not indicative of a urinary tract infection.

- Considered that antibiotic treatment alone may not be effective for patients who present a deep skin and soft-tissue infection that requires surgical intervention.

- Do not use antibiotics in the following cases:
  - Newly purulent wound (or an increase in purulence) as the only symptom
  - Increase local wound care
  - Influenza or other viral infections without bacterial superinfection
  - Aspiration without bacterial superinfection
